October 2, 2020

Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

SAND2020-10685 PE

2 Outline

1. Motivating Applications
2. General Problem Formulation
3. Randomize Sketching for State Compression
4. Fixed Rank Analysis
5. Adaptive Rank Algorithm
6. Numerical Results

3 Operational Applications

Secondary Oil Recovery

$$\max_{v,p,s,q} \text{NPV}(v,p,s,q)$$

subject to

$$v = -\mathbf{K}\lambda(s)(\nabla p - \rho G)$$

$$\nabla \cdot v = q/\rho$$

$$\phi \partial_t s + \nabla \cdot (f(s)v) = q$$

1. **Goal:** Determine injection rates that maximize the net present value of the reservoir.
2. **Problem Size:** The reservoir can span 10+ km per side $\implies 1000\text{km}^3$
A regular grid with $5\text{m} \times 5\text{m} \times 5\text{m}$ cells $\implies 8$ billion cells!
3. **Similar Applications:** Gas pipeline and energy network operations, financial portfolio optimization, optimal control of hypersonic vehicles, etc.

4 Optimal Design

Convolute Design for the Z-Machine (Inertial Confinement Fusion)

Goal: Minimize power loss – **current design experiences 20% power loss**

Similar Applications: Designing elastic structures with topology optimization, shape optimization for airplane wing design, etc.

Courtesy of Schlumberger

$$\min_{u, \theta} \frac{1}{2} \|u - d\|^2 + \alpha \varphi(\theta)$$

subject to

$$\partial_t (\rho(\theta) \partial_t u) - \nabla \cdot (\mathbf{K}(\theta) : \varepsilon) = s$$

$$\varepsilon = \frac{1}{2} (\nabla u + \nabla u^\top)$$

1. **Goal:** Determine subsurface rock properties that minimize data misfit.
2. **Problem Size:** **Typical marine surveys require many TBs of memory!**
3. **Similar Applications:** Parameter calibration, data assimilation, supervised learning for neural networks, etc.

$$\begin{aligned} \min_{z_n \in \mathbb{R}^m, u_n \in \mathbb{R}^M} & \sum_{n=1}^N f_n(u_{n-1}, u_n, z_n) \\ \text{subject to} & \quad c_n(u_{n-1}, u_n, z_n) = 0, \quad n = 1, \dots, N \end{aligned}$$

where $f_n : \mathbb{R}^M \times \mathbb{R}^M \times \mathbb{R}^m \rightarrow \mathbb{R}$ is the **cost function at time t_n** ,

$c_n : \mathbb{R}^M \times \mathbb{R}^M \times \mathbb{R}^m \rightarrow \mathbb{R}^M$ is the **dynamic constraint at time t_n** ,

$u_n \in \mathbb{R}^M$ is the **state/trajectory at time t_n** , and

$z_n \in \mathbb{R}^m$ is the **control/design/parameters at time t_n** .

E.g., continuous dynamic problem discretized in time (and space).

Our methods also work for time-independent control/design/parameters.

The **KKT conditions** for the full-space dynamic optimization problem are

$$c_n(u_{n-1}, u_n, z_n) = 0$$

$$(\mathbf{d}_2 c_N(u_{N-1}, u_N, z_N))^\top \lambda_N = -\mathbf{d}_2 f_N(u_{N-1}, u_N, z_N)$$

$$(\mathbf{d}_2 c_n(u_{n-1}, u_n, z_n))^\top \lambda_n + (\mathbf{d}_1 c_{n+1}(u_n, u_{n+1}, z_{n+1}))^\top \lambda_{n+1} = -\mathbf{d}_2 f_n(u_{n-1}, u_n, z_n) - \mathbf{d}_1 f_{n+1}(u_n, u_{n+1}, z_{n+1})$$

$$\mathbf{d}_3 f_n(u_{n-1}, u_n, z_n) + (\mathbf{d}_3 c_n(u_{n-1}, u_n, z_n))^\top \lambda_n = 0, \quad n = 1, \dots, N.$$

The new variables $\lambda_1, \dots, \lambda_N$ are **Lagrange multipliers** for the dynamic constraint.

Most algorithms (e.g., SQP, AL, etc.) require storage of $\{u_n\}_{n=1}^N$, $\{\lambda_n\}_{n=1}^N$ and $\{z_n\}_{n=1}^N$.

Storage Requirement: $\mathcal{O}(N(2M + m))$ floating point numbers

\implies Can be **huge** (e.g., TBs of memory)!

If $c_n(u_{n-1}, u_n, z_n) = 0$ has a unique solution $u_n = S_n(u_{n-1}, z_n)$ for each $z \in Z_{\text{ad}}$ and fixed initial state $u_0 \in \mathbb{R}^M$, $n = 1, \dots, N$, then we can equivalently solve

$$\min_{Z = \{z_n\}_{n=1}^N \in \mathbb{R}^{mN}} F(Z)$$

where the *reduced* objective function F is given by

$$F(Z) := f_1(u_0, S_1(u_0, z_1), z_1) + \sum_{n=2}^N f_n(S_{n-1}(u_{n-2}, z_{n-1}), S_n(u_{n-1}, z_n), z_n).$$

Storage Requirement: $\mathcal{O}(Nm)$ floating point numbers — typically, $m \ll M$.

Gradient Computation:

$$(\nabla F(Z))_n = \mathbf{d}_3 f_n(u_{n-1}, u_n, z_n) + (\mathbf{d}_3 c_n(u_{n-1}, u_n, z_n))^\top \lambda_n$$

where $\lambda_n \in \mathbb{R}^M$, $n = 1, \dots, N$ solves the **backward-in-time adjoint equation**

$$(\mathbf{d}_2 c_N(u_{N-1}, u_N, z_N))^\top \lambda_N = -\mathbf{d}_2 f_N(u_{N-1}, u_N, z_N)$$

$$\begin{aligned} (\mathbf{d}_2 c_n(u_{n-1}, u_n, z_n))^\top \lambda_n &= -\mathbf{d}_2 f_n(u_{n-1}, u_n, z_n) - \mathbf{d}_1 f_{n+1}(u_n, u_{n+1}, z_{n+1}) \\ &\quad - (\mathbf{d}_1 c_{n+1}(u_n, u_{n+1}, z_{n+1}))^\top \lambda_{n+1} \end{aligned}$$

Gradient computations requires entire state trajectory to solve adjoint equation!

1. **Checkpointing:** Store a handful of state snapshots in memory or to hard disk. Recompute state from snapshots during adjoint computation.

Griewank and Walther, *Algorithm 799: Revolve: An implementation of checkpointing for scientific computing and optimal control*, 2000.

Significant increase in computational cost!

1. **Checkpointing:** Store a handful of state snapshots in memory or to hard disk. Recompute state from snapshots during adjoint computation.

Griewank and Walther, *Algorithm 799: Revolve: An implementation of checkpointing for scientific computing and optimal control*, 2000.

Significant increase in computational cost!

2. **Model Reduction:** Project dynamic equation onto a low-order basis of the solution space (e.g., balanced truncation, POD, reduced basis, etc.).

Benner, Sachs and Volkwein, *Model order reduction for PDE constrained optimization*, 2014.

Difficult for nonlinear dynamics and requires significant code modification!

1. **Checkpointing:** Store a handful of state snapshots in memory or to hard disk. Recompute state from snapshots during adjoint computation.

Griewank and Walther, *Algorithm 799: Revolve: An implementation of checkpointing for scientific computing and optimal control*, 2000.

Significant increase in computational cost!

2. **Model Reduction:** Project dynamic equation onto a low-order basis of the solution space (e.g., balanced truncation, POD, reduced basis, etc.).

Benner, Sachs and Volkwein, *Model order reduction for PDE constrained optimization*, 2014.

Difficult for nonlinear dynamics and requires significant code modification!

3. **State Compression:** Compress dynamic trajectory using numerical compression techniques including nested meshes, PCA, Gramm-Schmidt and DFT.

Cyr, Shadid and Wildey, *Towards efficient backward-in-time adjoint computations using data compression techniques*, 2015.

Can be physics-dependent and often compresses time/space independently!

We apply **randomized sketching** to compress the $M \times N$ state trajectory matrix

$$U = (u_1 \mid \cdots \mid u_N) \in \mathbb{R}^{M \times N}.$$

Goal: Generate an **accurate** rank- r approximation of U using $\mathcal{O}(r(M + N))$ storage.

Matrix Sketching: Given the four **random linear dimension reduction maps**

$$\Upsilon \in \mathbb{R}^{k \times M}, \quad \Omega \in \mathbb{R}^{k \times N}, \quad \Phi \in \mathbb{R}^{s \times M}, \quad \text{and} \quad \Psi \in \mathbb{R}^{s \times N},$$

where $k := 2r + 1$ and $s = 2k + 1$, we define the sketch as the following three matrices

$$X := \Upsilon U \in \mathbb{R}^{k \times N} \quad \text{the co-range sketch;}$$

$$Y := U \Omega^\top \in \mathbb{R}^{M \times k} \quad \text{the range sketch;}$$

$$Z := \Phi U \Psi^\top \in \mathbb{R}^{s \times s} \quad \text{the core sketch.}$$

Tropp, Yurtserver, Udell and Cevher, *Streaming low-rank matrix approximation with an application to scientific simulation*, 2019.

Choice of Random Matrices: **Standard normal**, scrambled subsampled randomized Fourier transform, sparse sign, ...

Intuition:

- ▶ The range sketch $Y = U\Omega^\top$ consists of columns $U\omega_i$, which are independent random samples from $\text{range}(U)$.

Roughly speaking, Y captures the action of the **top k left singular vectors**.

- ▶ Similarly, the co-range sketch $X = \Upsilon U$ consists of rows $v_i^\top U$, which are independent random samples from $\text{range}(U^\top)$.

Roughly speaking, X captures the action of the **top k right singular vectors**.

- ▶ ***Roughly speaking***, the core sketch $Z = \Phi U \Psi^\top$ captures the **top k singular values**.

Online State Sketching:

Require: $X = 0, Y = 0, Z = 0$

1: **for** $n=1, \dots, N$ **do**

2: Given u_{n-1} and z_n , solve $c_n(u_{n-1}, u_n, z_n) = 0$ for u_n

3: Update $X \leftarrow X + \Upsilon u_n e_n^\top$

4: Update $Y \leftarrow Y + u_n (\Omega e_n)^\top$

5: Update $Z \leftarrow Z + (\Phi u_n) (\Psi e_n)^\top$

6: **end for**

Storage Requirement: Sketching requires $k(M + N) + s^2$ floating point numbers.

Online State Sketching:

Require: $X = 0, Y = 0, Z = 0$

- 1: **for** $n=1, \dots, N$ **do**
- 2: Given u_{n-1} and z_n , solve $c_n(u_{n-1}, u_n, z_n) = 0$ for u_n
- 3: Update $X \leftarrow X + \Upsilon u_n e_n^\top$
- 4: Update $Y \leftarrow Y + u_n (\Omega e_n)^\top$
- 5: Update $Z \leftarrow Z + (\Phi u_n) (\Psi e_n)^\top$
- 6: **end for**

Storage Requirement: Sketching requires $k(M + N) + s^2$ floating point numbers.

Recovery:

- 1: $(Q, R_2) \leftarrow \text{qr}(Y, 0)$
- 2: $(P, R_1) \leftarrow \text{qr}(X^\top, 0)$
- 3: $C \leftarrow (\Phi Q)^\dagger Z ((\Psi P)^\dagger)^\top$
- 4: $W \leftarrow CP^\top$
- 5: $u_n \approx QWe_n$

$$\begin{aligned} Q &\in \mathbb{R}^{M \times k}, & R_2 &\in \mathbb{R}^{k \times k} \\ P &\in \mathbb{R}^{N \times k}, & R_1 &\in \mathbb{R}^{k \times k} \\ & & C &\in \mathbb{R}^{k \times k} \\ & & W &\in \mathbb{R}^{k \times N} \end{aligned}$$

Storage Requirement: Recovery requires $k(M + N) + k^2$ floating point numbers.

**Theorem: Sketching Error Bound**

Let $\{\{U\}\}_r$ denote the sketch of U associated with the rank parameter r . Then,

$$\mathbb{E}_{\Upsilon, \Omega, \Phi, \Psi} \|U - \{\{U\}\}_r\|_F \leq \sqrt{6} \left(\sum_{i \geq r+1} \sigma_i^2(U) \right)^{\frac{1}{2}}.$$

The error is *expected* to be slightly larger than the best rank- r approximation!

Similar results exist for the probability of large deviation.

Tropp, Yurtserver, Udell and Cevher, *Streaming low-rank matrix approximation with an application to scientific simulation*, 2019.

Solve Adjoint Equation and Compute Gradient:

Require: Sketched state $\{\{U\}\}_r$.

- 1: Reconstruct $\tilde{\mathbf{u}}_{N-1}$ and $\tilde{\mathbf{u}}_N$ from $\{\{U\}\}_r$.
- 2: Compute $\tilde{\lambda}_N$ that solves $(\mathbf{d}_2 c_N(\tilde{\mathbf{u}}_{N-1}, \tilde{\mathbf{u}}_N, z_N))^\top \tilde{\lambda}_N = -\mathbf{d}_2 f_N(\tilde{\mathbf{u}}_{N-1}, \tilde{\mathbf{u}}_N, z_N)$.
- 3: Set $g_N = \mathbf{d}_3 f_N(\tilde{\mathbf{u}}_{N-1}, \tilde{\mathbf{u}}_N, z_N) + (\mathbf{d}_3 c_N(\tilde{\mathbf{u}}_{N-1}, \tilde{\mathbf{u}}_N, z_N))^\top \tilde{\lambda}_N$.
- 4: **for** $n = N - 1, \dots, 1$ **do**
- 5: Reconstruct $\tilde{\mathbf{u}}_{n-1}$ from $\{\{U\}\}_r$.
- 6: Compute $\tilde{\lambda}_n$ that solves

$$(\mathbf{d}_2 c_n(\tilde{\mathbf{u}}_{n-1}, \tilde{\mathbf{u}}_n, z_n))^\top \tilde{\lambda}_n = -\mathbf{d}_2 f_n(\tilde{\mathbf{u}}_{n-1}, \tilde{\mathbf{u}}_n, z_n) - \mathbf{d}_1 f_{n+1}(\tilde{\mathbf{u}}_n, \tilde{\mathbf{u}}_{n+1}, z_{n+1}) \\ - (\mathbf{d}_1 c_{n+1}(\tilde{\mathbf{u}}_n, \tilde{\mathbf{u}}_{n+1}, z_{n+1}))^\top \tilde{\lambda}_{n+1}.$$

- 7: Set $g_n = \mathbf{d}_3 f_n(\tilde{\mathbf{u}}_{n-1}, \tilde{\mathbf{u}}_n, z_n) + (\mathbf{d}_3 c_n(\tilde{\mathbf{u}}_{n-1}, \tilde{\mathbf{u}}_n, z_n))^\top \tilde{\lambda}_n$.
- 8: **end for**

Define the combined objective function and constraint by

$$f(U, Z) = \sum_{i=1}^N f_i(u_{i-1}, u_i, z_i) \quad \text{and} \quad c(U, Z) = \begin{pmatrix} c_1(u_0, u_1, z_1) \\ \vdots \\ c_N(u_{N-1}, u_N, z_N) \end{pmatrix}.$$

Assumptions:

Define the combined objective function and constraint by

$$f(U, Z) = \sum_{i=1}^N f_i(u_{i-1}, u_i, z_i) \quad \text{and} \quad c(U, Z) = \begin{pmatrix} c_1(u_0, u_1, z_1) \\ \vdots \\ c_N(u_{N-1}, u_N, z_N) \end{pmatrix}.$$

Assumptions:

1. For any bounded set $\mathcal{Z} \subset \mathbb{R}^{Nm}$, the set $\mathcal{U} = \{U \mid c(U, Z) = 0, Z \in \mathcal{Z}\}$ is bounded;

Define the combined objective function and constraint by

$$f(U, Z) = \sum_{i=1}^N f_i(u_{i-1}, u_i, z_i) \quad \text{and} \quad c(U, Z) = \begin{pmatrix} c_1(u_0, u_1, z_1) \\ \vdots \\ c_N(u_{N-1}, u_N, z_N) \end{pmatrix}.$$

Assumptions:

1. For any bounded set $\mathcal{Z} \subset \mathbb{R}^{Nm}$, the set $\mathcal{U} = \{U \mid c(U, Z) = 0, Z \in \mathcal{Z}\}$ is bounded;
2. There exists $0 < \sigma_0 \leq \sigma_1 < \infty$ such that for all $U \in \mathcal{U}$ and $Z \in \mathcal{Z}$
$$\sigma_0 \leq \sigma_{\min}(\mathbf{d}_1 c(U, Z)) \leq \sigma_{\max}(\mathbf{d}_1 c(U, Z)) \leq \sigma_1;$$

Define the combined objective function and constraint by

$$f(U, Z) = \sum_{i=1}^N f_i(u_{i-1}, u_i, z_i) \quad \text{and} \quad c(U, Z) = \begin{pmatrix} c_1(u_0, u_1, z_1) \\ \vdots \\ c_N(u_{N-1}, u_N, z_N) \end{pmatrix}.$$

Assumptions:

1. For any bounded set $\mathcal{Z} \subset \mathbb{R}^{Nm}$, the set $\mathcal{U} = \{U \mid c(U, Z) = 0, Z \in \mathcal{Z}\}$ is bounded;
2. There exists $0 < \sigma_0 \leq \sigma_1 < \infty$ such that for all $U \in \mathcal{U}$ and $Z \in \mathcal{Z}$
$$\sigma_0 \leq \sigma_{\min}(\mathbf{d}_1 c(U, Z)) \leq \sigma_{\max}(\mathbf{d}_1 c(U, Z)) \leq \sigma_1;$$
3. The functions $\mathbf{d}_1 c(U, Z)$, $\mathbf{d}_2 c(U, Z)$, $\mathbf{d}_1 f(U, Z)$ and $\mathbf{d}_2 f(U, Z)$ are Lipschitz continuous on $\mathcal{U} \times \mathcal{Z}$ with respect to U and the Lipschitz moduli are independent of $Z \in \mathcal{Z}$.

Define the combined objective function and constraint by

$$f(U, Z) = \sum_{i=1}^N f_i(u_{i-1}, u_i, z_i) \quad \text{and} \quad c(U, Z) = \begin{pmatrix} c_1(u_0, u_1, z_1) \\ \vdots \\ c_N(u_{N-1}, u_N, z_N) \end{pmatrix}.$$

Assumptions:

1. For any bounded set $\mathcal{Z} \subset \mathbb{R}^{Nm}$, the set $\mathcal{U} = \{U \mid c(U, Z) = 0, Z \in \mathcal{Z}\}$ is bounded;
2. There exists $0 < \sigma_0 \leq \sigma_1 < \infty$ such that for all $U \in \mathcal{U}$ and $Z \in \mathcal{Z}$

$$\sigma_0 \leq \sigma_{\min}(\mathbf{d}_1 c(U, Z)) \leq \sigma_{\max}(\mathbf{d}_1 c(U, Z)) \leq \sigma_1;$$
3. The functions $\mathbf{d}_1 c(U, Z)$, $\mathbf{d}_2 c(U, Z)$, $\mathbf{d}_1 f(U, Z)$ and $\mathbf{d}_2 f(U, Z)$ are Lipschitz continuous on $\mathcal{U} \times \mathcal{Z}$ with respect to U and the Lipschitz moduli are independent of $Z \in \mathcal{Z}$.

Under these assumptions, we can show that

$$\|g - \nabla F(Z)\| \leq \kappa_1 \underbrace{\|c(\{\{U\}\}_r, Z)\|}_{\text{state residual}} \quad \text{and} \quad \mathbb{E} \|g - \nabla F(Z)\| \leq \sqrt{6\kappa} \left(\sum_{i \geq r+1} \sigma_i^2(U) \right)^{\frac{1}{2}}.$$

- ▶ **Idea:** Use approximate gradient within a **derivative-based optimization algorithm**. For example, gradient descent, nonlinear CG, Newton–Krylov method, etc.
- ▶ If the rank parameter r is sufficiently large, then gradient error **may be negligible**.
- ▶ For Newton–Krylov, applying the Hessian to a vector requires **a linearized forward-in-time solve** and **a linearized backward-in-time solve**.
- ▶ Can **approximately** apply the Hessian to a vector by **sketching the adjoint as well as the trajectories from the additional solves**.

Require: Initial guess $Z^{(0)} \in \mathbb{R}^{Nm}$ and target rank r . Algorithmic parameters: $\Delta^{(0)} > 0$ and $0 < \eta_0 \leq \eta_1 < \eta_2 < 1$.

1: **for** $\ell = 0, 1, 2, \dots$ **do**

2: Solve state equation and sketch solution $\{\{U^{(\ell)}\}\}_r$.

3: Compute gradient approximation $g^{(\ell)} \approx \nabla F(Z^{(\ell)})$ using sketched state $\{\{U^{(\ell)}\}\}_r$.

4: Choose $B^{(\ell)} \in \mathbb{R}^{Nm \times Nm}$ to be an approximation of the Hessian $\nabla^2 F(Z^{(\ell)})$.

5: Compute $S^{(\ell)} \in \mathbb{R}^{Nm}$ that approximately solves the trust-region subproblem

$$\min_{S \in \mathbb{R}^{Nm}} \frac{1}{2} \langle S, B^{(\ell)} S \rangle + \langle S, g^{(\ell)} \rangle \quad \text{subject to} \quad \|S\| \leq \Delta^{(\ell)}.$$

6: Compute the ratio of actual and predicted reduction

$$\rho^{(\ell)} = \frac{F(Z^{(\ell)}) - F(Z^{(\ell)} + S^{(\ell)})}{-\frac{1}{2} \langle S^{(\ell)}, B^{(\ell)} S^{(\ell)} \rangle - \langle S^{(\ell)}, g^{(\ell)} \rangle}.$$

7: Set $Z^{(\ell+1)} = \begin{cases} Z^{(\ell)} & \text{if } \rho^{(\ell)} \leq \eta_0 \\ Z^{(\ell)} + S^{(\ell)} & \text{otherwise.} \end{cases}$

8: Choose $\Delta^{(\ell+1)} \in \begin{cases} (0, \Delta^{(\ell)}) & \text{if } \rho^{(\ell)} \leq \eta_1 \\ \{\Delta^{(\ell)}\} & \text{if } \rho^{(\ell)} \in (\eta_1, \eta_2) \\ (\Delta^{(\ell)}, \infty) & \text{otherwise.} \end{cases}$

4. Evaluate state residual while solving adjoint equation.

If bound is violated, increase r , re-solve state equation and re-sketch state!

5. Hopefully sufficiently large r is determined after a handful of updates.

May run out of memory if rank of state is too large!

**Theorem: Convergence of Adaptive-Rank Trust-Region Method**

Suppose there exists a bounded, open, convex set $\mathcal{Z} \subset \mathbb{R}^{Nm}$ such that $Z^{(\ell)} \in \mathcal{Z}$ for all ℓ . Suppose F is bounded below and twice continuously differentiable on \mathcal{Z} . Moreover, assume that $\nabla^2 F(\cdot)$ is uniformly bounded on \mathcal{Z} and that $B^{(\ell)}$ is bounded independently of ℓ . Then,

$$\liminf_{\ell \rightarrow \infty} \|g^{(\ell)}\| = \liminf_{\ell \rightarrow \infty} \|\nabla F(Z^{(\ell)})\| = 0.$$

Kouri and Ridzal, *Inexact trust-region methods for PDE-constrained optimization*, 2018.

“Simple” Control Constraints: Constraints with *easy-to-compute* projections such as

$$a_0 \leq CZ \leq a_1 \quad \text{and} \quad DZ = b.$$

Only need to modify trust-region subproblem to account for constraints in the set Z_{ad} , i.e.,

$$\min_{S \in \mathbb{R}^{Nm}} \frac{1}{2} \langle S, B^{(\ell)} S \rangle + \langle S, g^{(\ell)} \rangle \quad \text{subject to} \quad Z^{(\ell)} + S \in Z_{\text{ad}}, \quad \|S\| \leq \Delta^{(\ell)}.$$

Garreis and Ulbrich, *An inexact trust-region algorithm for constrained problems in Hilbert space and its application to the adaptive solution of optimal control problems with PDEs*, 2019.

“Simple” Control Constraints: Constraints with *easy-to-compute* projections such as

$$a_0 \leq CZ \leq a_1 \quad \text{and} \quad DZ = b.$$

Only need to modify trust-region subproblem to account for constraints in the set Z_{ad} , i.e.,

$$\min_{S \in \mathbb{R}^{Nm}} \frac{1}{2} \langle S, B^{(\ell)} S \rangle + \langle S, g^{(\ell)} \rangle \quad \text{subject to} \quad Z^{(\ell)} + S \in Z_{\text{ad}}, \quad \|S\| \leq \Delta^{(\ell)}.$$

Garreis and Ulbrich, *An inexact trust-region algorithm for constrained problems in Hilbert space and its application to the adaptive solution of optimal control problems with PDEs*, 2019.

General Constraints: Use augmented Lagrangian, log barrier, etc. to penalize general nonlinear constraints such as

$$g(U, Z) = 0 \quad \text{and} \quad h(U, Z) \leq 0.$$

Apply the adaptive rank algorithm to solve the penalized subproblems

$$\min_{Z \in \mathbb{R}^{Nm}} F(Z) + \wp^{(\ell)}(Z).$$

Let \mathcal{L} be a uniformly bounded and coercive linear operator, B a bounded linear operator and β a continuous linear functional. Consider the optimal control problem

$$\begin{aligned} \min_{u, z} \quad & \frac{1}{2} \int_0^T \|u - w\|^2 dt + \frac{\alpha}{2} \int_0^T \|z\|^2 dt \\ \text{subject to} \quad & \partial_t u + \mathcal{L}(t)u = \beta(t) + Bz \\ & u(0) = u_0. \end{aligned}$$

Discretization

1. Continuous finite elements in space and implicit Euler in time.
2. Similar results hold for trapezoidal (Crank-Nicolson) and explicit Euler.

Stability Estimates: C_n^1, C_n^2 are positive constants that depend on the time step δt_n

$$\|\tilde{u}_n - u_n\| \leq C_n^1 \sum_{i=1}^n \|c_i(\tilde{u}_{i-1}, \tilde{u}_i, z_i)\| \quad \text{and} \quad \|\tilde{\lambda}_n - \lambda_n\| \leq C_n^2 \sum_{i=1}^n \|c_i(\tilde{u}_{i-1}, \tilde{u}_i, z_i)\|.$$

Using these estimates, we can prove convergence of adaptive rank algorithm!

Let $D = (0, 0.5) \times (0, 0.2)$ with boundary ∂D and consider the optimal control problem

$$\min_{u, z} \frac{1}{2} \int_0^T \int_D |u - 1|^2 dxdt + \frac{\alpha}{2} \int_0^T \int_D |z|^2 dxdt$$

subject to

$$\partial_t u - \gamma \Delta u + \mathbf{v} \cdot \nabla u + u = \beta + z \quad \text{in } (0, T) \times D$$

$$\gamma \nabla u \cdot \mathbf{n} = 0 \quad \text{on } (0, T) \times \partial D$$

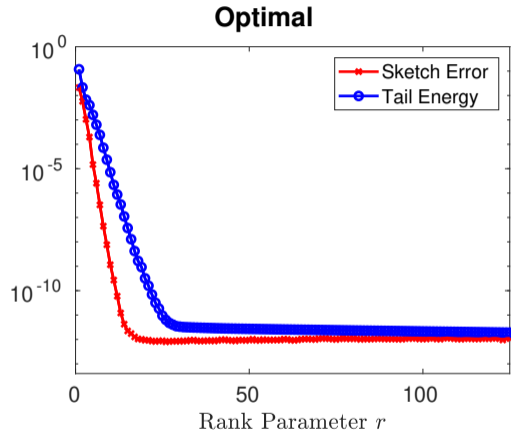

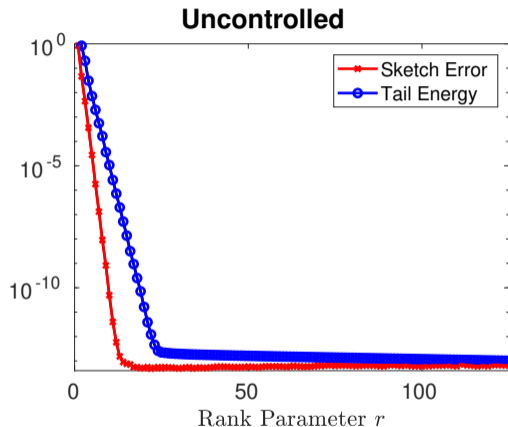

$$u(0) = 0 \quad \text{in } D,$$

where $\alpha = 10^{-4}$, $\gamma = 0.1$, $\mathbf{v}(x) = (7.5 - 2.5x_1, 2.5x_2)^\top$, and

$$\beta(x) = \begin{cases} 1 & \text{if } \|x - (0.1, 0.1)^\top\| \leq 0.07 \\ 0 & \text{otherwise.} \end{cases}$$

Spatial Discretization: Q1 finite elements on a uniform mesh of 60×20 quadrilaterals.

Temporal Discretization: Implicit Euler with 500 equal time steps.

Sketching error averaged over 20 realizations and **tail energy** for the uncontrolled state (left) and the optimal state (right). Recall that the rank of the sketch is $k = 2r + 1$.

Termination Criterion: $\|g^{(\ell)}\| \leq 10^{-7}$ or $\ell > 20$.

Rank Increase Function: $r \leftarrow \max\{r + 2, \lceil (b - \log \tau)/a \rceil\}$ with $a = 2.6125$, $b = 2.4841$.

Adaptive-rank algorithm reduced memory requirement 23.14-fold!

We consider the optimal flow control problem

$$\min_z \int_0^T \left\{ \int_{\partial C} \left(\frac{1}{\text{Re}} \frac{\partial \mathbf{v}}{\partial n} - pn \right) \cdot (z\boldsymbol{\tau} - \mathbf{v}_\infty) \, dx + \frac{\alpha}{2} z(t)^2 \right\} dt,$$

where the velocity/pressure $(\mathbf{v}, p) : [0, T] \times D \rightarrow \mathbb{R}^2 \times \mathbb{R}$ solves the Navier-Stokes equations

$$\begin{aligned} \frac{\partial \mathbf{v}}{\partial t} - \frac{1}{\text{Re}} \Delta \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} + \nabla p &= 0 && \text{in } (0, T) \times D \setminus C \\ \nabla \cdot \mathbf{v} &= 0 && \text{in } (0, T) \times D \setminus C \\ \frac{1}{\text{Re}} \frac{\partial \mathbf{v}}{\partial n} - pn &= 0 && \text{on } (0, T) \times \Gamma_{\text{out}} \\ \mathbf{v} &= \mathbf{v}_\infty && \text{on } (0, T) \times \partial D \setminus \Gamma_{\text{out}} \\ \mathbf{v} &= z\boldsymbol{\tau} && \text{on } (0, T) \times \partial C \end{aligned}$$

Goal: Minimize the **power required to overcome the drag** on C by rotating C .

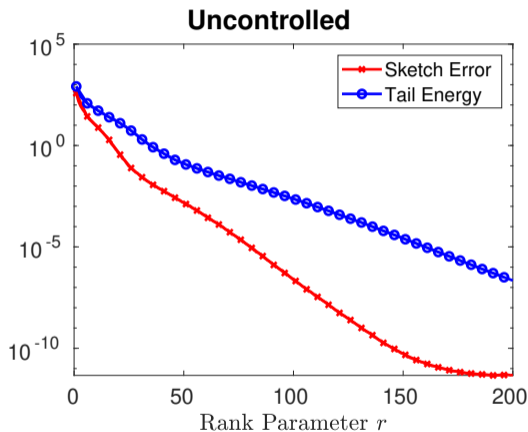

Problem Data: $D = (-15, 45) \times (-15, 15)$, $C = B_{1/2}$, $\text{Re} = 200$, $T = 20$, and tangent vector

$$\tau(x) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} (x - x_0), \quad x \in \partial C.$$

Spatial Discretization: Q2–Q1 finite elements.

Temporal Discretization: Implicit Euler with 800 equal time steps.

**Initial Vorticity ($t = 0$)****Initial Velocity ($t = 0$)****Controlled Vorticity ($t = 20$)****Controlled Velocity ($t = 20$)**

Sketching error averaged over 20 realizations and **tail energy** for the uncontrolled state (left) and the optimal state (right). Recall that the rank of the sketch is $k = 2r + 1$.

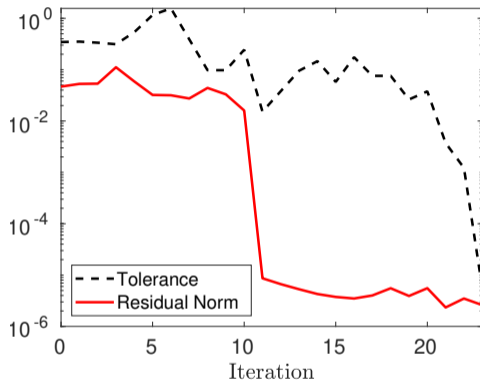

Termination Criterion: $\|g^{(\ell)}\| \leq 10^{-5}$ or $\ell > 40$.

Rank Increase Function: $r \leftarrow 2r$.

*The rank 8, 16, and 32 experiments exceeded the maximum number of iterations.

Left: Sketch rank as a function of iteration of adaptive-rank algorithm. **Right:** Required gradient inexactness tolerance and computed residual norm as functions of iteration.

Adaptive-rank algorithm reduced memory requirement 5.88-fold!

- ▶ **Numerical solution** of dynamic optimization is **expensive** and requires **careful memory management**.
- ▶ We **compress** the dynamic state using **randomized matrix sketching**.
- ▶ State compression using sketching is **lossy** and results in **inexact gradients**.
- ▶ Introduced provably convergent algorithm to handle gradient inexactness. Algorithm adaptively learns the rank of the optimal state — **May run out of memory for non-low-rank states!**
- ▶ Numerical examples suggest **~5–70-fold reduction** in memory requirement.
